# Which segment of the network?

## Terminals:

Already energy-efficient  
by design

## Core devices:

- Energy-hungry
- Not many
- Very critical
- Handle aggregate traffic

POLITECNICO  
DI TORINO

DET  
Department of Electronics and Telecommunications

Marco Ajmone Marsan

# Which segment of the network?

## Access network:

- Energy-hungry
- Many devices
- Some redundancy
- Less critical than core devices
- Very close to the user, hence high traffic variability

# Mobile networks

According to an estimate of Nokia Siemens Networks, worldwide...

$$3 \text{ billion} \times 0.1 \text{ W} = \\ \mathbf{0.3 \text{ GW}}$$

$$3 \text{ million} \times 1.5 \text{ kW} = \\ \mathbf{4.5 \text{ GW}}$$

$$10,000 \times 10 \text{ kW} = \\ \mathbf{0.1 \text{ GW}}$$

POLITECNICO  
DI TORINO

DET  
Department of Electronics and Telecommunications

Marco Ajmone Marsan

# Energy efficient solutions

- Traditionally, little attention to consumption in the design of the devices and of the network
- Many inefficiencies derive from the combination of
  - little load proportionality of consumption
  - due to traffic variability, long periods under low to medium load

# Energy efficient solutions

- Consume energy for capacity *deployment*, not for capacity *usage*
- Many solutions try to make capacity *adaptive* to load
  - Use of sleep modes for the BSs
  - Network sharing
  - Resource on demand architectures
- Saving of up to 40% can be achieved,

**is this enough?**

POLITECNICO  
DI TORINO

DET  
Department of Electronics and Telecommunications

Marco Ajmone Marsan

# Micro and macro effects of energy efficiency

Jevons paradox:

**Increase of energy efficiency** to produce  
a good/service

reduces cost of the production and, hence, its price

increases the demand

**increases the energy consumption**

POLITECNICO  
DI TORINO

DET  
Department of Electronics and Telecommunications

Marco Ajmone Marsan

institute  
**imdea**  
networks

# From energy efficient networking to sustainable networking

- Energy efficiency is good since, through cost reduction, it leads to
  - Higher production → better quality of life for more people
  - Reduction of price increase and energy shortage
  - Global environmental advantage if coupled with green taxes to keep the price constant
- but, for sustainability,  
it must be coupled with new energy generation principles  
**(RES – Renewable Energy Sources)**

# Powering BSs with renewables

- **Zero grid-Electricity Networking (ZEN)**

BSs rely purely on renewable energy sources and are not connected to a power grid

- Can acquire limited amounts of energy from (intermittent) local generators exploiting **renewable sources**
- Any energy surplus is stored in a **battery**
- The BS can operate also in periods of low or no production, as long as energy is available, but it is forced to switch off when the battery is depleted

- **Hybrid** systems that, when battery is depleted, rely also on the power grid (or a secondary generator)

# Powering BSs with renewables

- Power BSs with Renewable Energy Sources
  - ❑ To deploy networks where the power grid does not exist, is not ubiquitous or is not reliable
  - ❑ To achieve extremely low carbon footprints
  - ❑ To reduce operational cost
  - ❑ To survive to power grid outages or natural disasters which damage the power grid

Possible scenarios:

1. New opportunities for the deployment of networks in **emerging regions**

POLITECNICO  
DI TORINO

DET  
Department of Electronics and Telecommunications

Marco Ajmone Marsan

# Possible scenarios: Emerging areas

# Possible scenarios: Emerging areas

- Expected expansion of mobile networks in rural regions in Africa and Asia
- Most of the BSs are powered with **diesel generators**
  - Costly (especially due to fuel transportation)
  - Bad for the environment

**imdea**  
networks

# Hybrid systems definition

- Define parameter PT:  
**percentage of time the battery charge is above 30%**
- $PT = 100\%$  (ZEN, pure PV): guarantee that the battery charge is above 30% for 100% of the time in a year
- $PT < 100\%$  (hybrid system): The battery is above 30% for a percentage of time equal to PT, buy energy comes from the power grid when the battery charge becomes 0
- Lower values of PT  $\rightarrow$  more energy from the grid
  - We consider PT in  $\{70,80,90,100\}\%$

# Methodology: The scenario

- Consider 10 year period
- Choose a location
- Consider a typical BS – macro LTE
  - Energy consumption
  - Traffic (from a real network)

} → energy need
- Consider evolution of parameters in 10 years
  - Traffic increases by 50% Compound Average Growth Rate (CAGR)
  - PV panel efficiency decreases by 1% per year
  - Electricity price increases by 3% per year

# Methodology: Dimension the powering system

For each year of the 10 year period

- Compute the BS energy need
- For increasing size of PV panel
  - Simulate daily energy production
  - Find the min no. of needed batteries by simulating battery charge and discharge over the whole year
  - Compute the cost of PV panels and batteries
- Choose the combination of PV panel size and no. of batteries that minimizes the cost
- Simulate 10 year, compute cost of batteries replacement
- Compute overall cost (CAPEX+OPEX)

**→ Select the minimum cost system**
